

3.6 Pair programming

Pair programming is an agile software development technique where two developers collaborate at one workstation, with one acting as the "driver" (writing code) and the other as the "navigator" (reviewing, thinking ahead, guiding), frequently switching roles to improve code quality, share knowledge, and solve problems more effectively.

This continuous, real-time feedback loop catches errors early, enhances design, and speeds up learning, often leading to better, faster development despite using two people.

Key Roles

- **Driver**: Physically types the code, focusing on the immediate implementation.
- **Navigator**: Observes, thinks about the overall strategy, suggests improvements, and ensures best practices are followed.
